TOPIC TAGS: lunar radiation, artificial Moon, modulation radiotele-

Temperature, lunar phase

ABSTRACT: A superheterodyne modulation radiometer with an input parametric amplifier was used to measure the lunar phase in the autumn of 1962 in the Crimea at $\lambda = 1.5$ cm. The threshold of radiometer sensitivity was 0.15K at an output-meter time constant of $\tau = 15$ sec. The antenna system consisted of a parabolic reflector 11.5 m in diameter and an exciter for the reception of horizontally polarized waves. The width of the antenna radiation pattern was 49 minutes at the 3-db level. To compensate for the background signal, the second input of the radiometer was connected to a horn radiator

directed toward the zenith. The radio emission of the Moon was compared to that of the black standard disc located in the Fraunhofer region of the antenna at an elevation of 19 degrees and distance from the telescope of 142.4 m. The diameter of the black standard disc was selected in such a way that its angular dimensions were close to the average angular dimension of the Moon. The results

TITLE: Observation of the radio eclipse of the moon at millimeter wavelengths

no. 2. 1965, 219-228

SOURCE: IZV. Radiofizika, v. 9, no. 5, 1977, p. 1000

TOPIC TAGS: radioastronomy, lunar eclipse, brightness temperature, lunar surface material

ABSTRACT: The radio emission from the moon was measured during the eclipses of 7 July and 30 December 1963, by a procedure in which the antenna was periodically compared with a standard signal which consisted of the difference between the emission of a section of the sky of fixed altitude and a mountain slope having a temperature close to that of the surrounding air. The work was done at Mt. Aragats in Armenia (3250 m) on 7 July, and in Usurys (Priamorskiy kray) on 30 December. Several refinements were introduced to correct for the variation of the emission of the eclipse. The maximum relative

level of effective temperature was 71.7.

TITLE: On the effect of the preparation conditions on the formation of traps in ZnS and ZnO base phosphors and the influence of predecomposition phenomena in solid solutions of Cu_2O in ZnS on their luminescence /Report, Fourteenth Conference on Luminescence Held in Riga, 16-23 September 1965/

SOURCE: AN SSSR. Izvestiya. Seriya fizicheskaya, v. 30, no. 4, 1966, 637-643

TOPIC TAGS: luminescence, crystal phosphor, zinc sulfide, current carrier, *lumino-phor*

ABSTRACT: Introduction of new experimental methods has increased rather than reduced the disagreement among different investigators regarding the structure of zinc sulfide luminophors. On the basis of previous investigations of glow curves and the polarity of the photocurrent carriers the authors showed that for the most part the discrepancies are due to inadequate control of the synthesis conditions, i.e., that the phosphors studied by different groups differed as regards structure owing to unintentional variations of the preparation conditions. Experiments show, for example, that truly self-activated ZnS exhibits only one glow curve peak, but that if the compound

Cord 1/2

L 26491-66

ACC NR: AP6013070

is exposed to oxygen, even at low pressure, during heating a second glow-curve peak appears and this is accompanied by change in the polarity of the photocurrent carriers (from n to p). Various experiments were carried out with pure, self-activated and impurity-activated ZnS and ZnO (including surface oxidized specimens) and several series of glow curves are reproduced. Data on the polarity of the current carriers in photoconductivity are also adduced. The curves and data demonstrate the effects of the synthesis conditions. A series of phosphors was prepared by heating different mixtures of ZnS with Cu_2S without flux at 1000°C , followed by reheating with quartz powder (to prevent caking) in sealed tubes at 1050°C . These ZnS:Cu phosphors were studied immediately after preparation, after various heat treatments and after storage for some months at 20° . Their attributes differed considerably, again indicating the importance of synthesis and other conditions. It is pointed out that understanding of the peculiarities of the complicated chemical system constituted by copper-activated zinc sulfide luminophors requires further thorough investigation of the ZnS- Cu_2S -Cu system. Kinetics of the polymerization of vinyl acetate in the presence of benzoyl peroxide in benzene solution. S. Kamenskaya and S. Medvedev. *Acta Physicochim. U.S.S.R.* 12, 865-88 (1940) (in Russian). -- Exptl. data on the polymerization of vinyl acetate in concn. from 1 to 4 M, in the presence of 0.04 to 0.40 M benzoyl peroxide in benzene soln. at temps. from 5° to 85° and the effect

thereon of the surface are given in 11 tables and 1 fig. The primary reaction is formation of a vinyl acetate-benzoyl peroxide complex which on reaction with the monomer initiates the primary active centers. The reaction is completely homogeneous. The energy of activation is 25.6 Cal. The reaction const. is given by $d[A]/dt = K_p[A]^{1/2}[B]^{1/2}$ with $K_p \times 10^3 = 22.5$ at 85°, 7.88 at 75°, 1.46 at 60°, 0.423 at 50°. The av. reaction chain length and the degree of polymerization are not the same, because the latter depends also upon reactions between growing radicals and the solvent mol.; it varies with the solvent, and in a purely thermal reaction is independent of the chain length. Benzoyl peroxide in benzene soln. decomposes with an energy of activation of 29.4 Cal. In the polymerization of vinyl acetate this decompos. does not obey the Arrhenius equation. The equation $\eta_{sp}/c = k[A]/(1 + g[A][B]^{1/2})$ is derived for the change of the degree of polymerization with the concn. of the soln., where $k = 2.44$, $g = 4.8$. The equation is well satisfied by the exptl. data. P. H. R.

Nature of branching reactions in the radical polymerization of alkenes. A. D. Alkin, S. N. Kamenskaya, and S. S. Kiselev. (L. Ya. Kurnov Institute, Moscow). *Zhur. Fiz. Khim.* 27, 1601-6 (1953); *cf. C.A.* 45, 3227c. The initial rates of copolymerization (r) of vinyl acetate (I) with 1-pentene (II) and 2-pentene (III); and those of polymerization of I, II, and III separately, all in the presence of benzoyl peroxide at 60°, were studied by means of a dilatometer. The limits of copolymers formed, as well as values of r , are tabulated as functions of the initial mole fraction of I. The rate constants for copolymerization of I-II and I-III are about 8100 and 6000 l./mole sec., resp. The reaction is inhibited by pentenes; this is due to the formation of allyl-type radicals. The polymerization of 1,3-butadiene is discussed. The most probable course of this reaction is through chain transmission of H atoms between monomers.

Investigation of copolymerization of hexadecyl and methyl acrylates in a toluene solution. S. N. Kamenskaya, A. S. Alkin, and S. S. Medvedev. *Dokl. Akad. Nauk S.S.S.R.* 106, 855-8 (1956); *et. C.A.* 45, 3227e. The relative reactivity of polymerization of 2 chemically similar monomers and their copolymerization was studied on the basis of the results reported before (*loc. cit.*). Me acrylate was purified by washing, drying, and distn. at 33-9° and 1.4 mm. Hg. Ether distd. from the monomer was used in its polymerization, doing away with the induction period. Hexadecyl acrylate was synthesized from hexadecanol and Me acrylate in the presence of *p*-toluenesulfonic acid. The ester was distd. in vacuo in the presence of metallic Cu, and the 155-60° fraction at 1.4 mm. Hg, m.p. 24°, $n_D^{20} = 1.4509$, $d_4^{20} = 0.859$, was collected. Pure Bz_2O_2 was used as the reaction initiator. For copolymerization, a toluene soln. with the monomer concn. of 1.5 moles/l. was used. The polymerization rate was observed dilatometrically, at $50 \pm 0.05^\circ$. The hexadecyl acrylate polymerization rate was found to be 2.3 times greater than of Me acrylate, and this rate was found to be the same at lower concns. of monomers. The copolymerization rate was calcd. by using the previously derived formula, which involved the use of the individual polymerization rates of the monomers, and the coeff. k which characterizes the ratio of the rate of the constants of the individual monomers polymerization initiation. The value of k was found to be 6 from the kinetic data, and nearly the same value from the av. of polymerization. By assuming the value for the Me acrylate chain growth rate $K_{A.A} = 10^6 \text{ sec}^{-1}$ (Matheson, *et al.*, *C.A.* 46, 1832e), the values for $K_{A.A} = 1538$; $K_{H.H} = 1597$; $K_{A.H} = 1731$; and $K_{H.A} = 1256$. TITLE: Determination of the Operating Parameters of Germanium Power Rectifiers (Opredeleniye rabochikh parametrov silovykh germaniyevykh ventiley)

PERIODICAL: Izvestiya Vysshikh Uchebnykh Zavedeniy, Fizika, 1958, Nr 4, pp 37-42 (USSR)

ABSTRACT: Paper read at the Inter-University Conference on Dielectrics and Semi-conductors, Tomsk, February, 1958. Generally, the limit value of the permissible current and of the reverse voltage of a given rectifier in a rectifying circuit are determined purely experimentally. For germanium rectifiers, this method is not particularly suitable because it involves testing to destruction of a large number of rectifiers which is very expensive and, since the characteristics of germanium rectifiers show high degrees of scattering, such test results are not reliable enough. Therefore, it is of interest to develop a non-destructive method of determining the operating parameters of such rectifiers. In para.1 the authors deal with the temperature characteristics of such rectifiers. The loading is limited by the

Card1/5

Determination of the Operating Parameters of Germanium Power Rectifiers

SOV/139-58-4-5/30

pn-transition temperature. The characteristics for the current flow in the reverse direction at various temperatures are graphed in Fig.1; for a given temperature the direct proportionality between the current and the voltage is disturbed from a certain voltage onwards and the curves form a bend beyond which operation is dangerous, since the slightest increase in voltage leads to a sharp increase of the reverse current which in turn causes intensive heating. Thus, on each curve a limit point can be marked off which corresponds to the bend of the reverse characteristic, by means of a method which is described in the paper; the curve which joins all these points is referred to as the curve of limit voltages at various temperatures. During normal operation with a given cooling system, the reverse current can be measured and the reverse voltage corresponding to this current. From such measurements and the family of curves of reverse current vs. reverse voltage for various temperatures, it is possible to determine the real temperature of the pn-transition and also to elucidate the dependence of this

Card2/5

Determination of the Operating Parameters of Germanium Power Rectifiers SOV/139-58-4-5/30

obviously depend on the cooling temperature. There is reason to assume that the critical current intensities at cooling temperatures above 0°C will be considerably higher than the fusion of the solder by means of which the current leads are soldered on and, therefore, determination of the critical current intensity according to the derived formulae has no practical importance. The derived relations permit determining the limit parameters of the rectifier. These relations are correct for the static conditions of operation of the valves. The variations in the current intensity with the progress of time is not taken into consideration and this is justified for very slowly varying currents and also for currents which change very rapidly when the average values have to be applied. If the speed of the thermal changes is commensurate with the speed of the changes of the current intensity, the time dependence of the current intensity has to be taken into consideration in the equations and this will complicate the equations. In this case the conditions of (static) stability cannot be justified, since

Card 4/5

SOV/139-58-4-5/30

Determination of the Operating Parameters of Germanium Power Rectifiers

the process of temperature rise may stop as a result of a rapid drop in the current intensity. In this case it will probably be necessary to introduce the concept of dynamic stability.

TITLE: Certain Problems of Technology and the Volt-Ampere Characteristics of Germanium Power Rectifiers (Nekotoryye voprosy tekhnologii i vol't-ampernyye kharakteristiki silovykh germaniyevykh ventiley)

PERIODICAL: *Izvestiya vysshikh uchebnykh zavedeniy, fizika*, 1958, Nr 5, pp 35-40 (USSR)

ABSTRACT: This paper was presented at the Conference of Higher Educational Establishments on Dielectrics and Semiconductors, Tomsk, February, 1958. Preparation of germanium power diodes involves the following operations: 1) cutting of germanium monocrystals and polishing of the resulting plates; 2) etching and drying of the plates; 3) deposition of an indium layer; 4) alloying (production of a p-n junction); 5) assembly and attachment of contacts; 6) final assembly. To cut germanium monocrystals the authors used abrasive discs KZ-180 (dimensions 100 x 0.18 x 20 mm) produced by the Leningrad Experimental Abrasive Works. Monocrystals were cut at 3100 rpm of the abrasive disc; water was used as the coolant.

Card 1/5

SOW/139-28-5-7/35

Certain Problems of Technology and the Volt-Ampere Characteristics
of Germanium Power Rectifiers

The abrasive disc thickness was 0.18 mm and the thickness of the cut was 0.2 mm. Surfaces of the resulting plates were so smooth that no polishing was necessary. This method of cutting made it possible to produce a plate of 20 mm dia in 2-3 min. The plates were etched in boiling hydrogen peroxide which had a few drops of KOH added to it. After etching the plates were washed 3 times in boiling distilled water and then dried at 60-70°C for 30 min to 1 hour. An indium layer was deposited in vacuo at 3×10^{-5} mm Hg (saturated vapour pressure of indium). Deposition took 2 hours and the indium temperature was 860°C. The edge of each germanium plate was shielded from the indium so as to form a ring of clear surface. The p-n junction was produced, using the apparatus shown in Fig.1. A tin plate 0.15 mm thick was placed at the bottom of a graphite cylinder. On top of the tin, a germanium plate (0.5 - 0.8 mm thick) was placed in such a way that its clear side (with no indium) was in direct contact with tin. A second graphite cylinder was then placed on top of the germanium plate; the walls of this cylinder were of such a thickness as to cover exactly the clear ring referred to above. Inside this second cylinder an indium plate was placed on top

Card 2/5

SOV/139-58-5-7/35

Certain Problems of Technology and the Volt-Ampere Characteristics of Germanium Power Rectifiers

of the germanium plate and it was pressed down with a press of stainless steel which produced a pressure of 10 g/cm^2 . The whole assembly was placed in a vacuum chamber and heated by means of an electrical furnace. The thermal treatment consisted of the following cycles: a) heating from 20°C to

$550\text{--}560^\circ\text{C}$ in 30 to 40 min, b) two minutes at $550\text{--}560^\circ\text{C}$,

c) cooling from 550°C to room temperature in about 6 hours. The next stage was the attachment of contacts and the assembly into a casing. This can be seen from Fig.2 which gives the cross-section of the complete rectifier. Base 3 and the upper contact 7 had Kovar plates attached to them; these plates were covered outside with an Sn-Pb-Bi 19-31-50% alloy which melts at 94.5°C . The upper contact 7 was connected with the upper terminal 1 by means of a spring 9. The germanium rectifier plate was placed with its tinned side in contact with the base 3. The upper contact 7 was placed

Card 3/5

84/155-58-5-7/35

Certain Problems of Technology and the Volt-Ampere Characteristics of Germanium Power Rectifiers

on top of the germanium plate and pressed down by means of the spring 9 . The whole assembly was heated to 95-100°C for a short time in order to solder the contacts 3 and 7 to the indium and tin electrodes of the rectifier. The rectifier assembly was then dried, a glass cylinder 8 was placed round it and the interior was filled with a silicon oil. A cover 2 was screwed on and a cooling plate 4 was attached. The complete rectifier is shown in Fig.3. The quality of the indium-germanium contact was studied by etching away the indium and examining the junction surface under a microscope. It was found (Fig.4) that alloying was not uniform but consisted of separate patches with a considerable portion of the junction area not wetted by indium. The forward and reverse volt-ampere characteristics of the power germanium diodes so produced were typical semiconductor curves. To obtain reliable volt-ampere characteristics, the rectifier was placed in a thermostat and only short voltage pulses were applied in the measurements (the upper curve in Fig.5). Application of a constant voltage even for a short time produced considerable amounts of heat inside the rectifier itself and this affected the results (the lower

curve in Fig.5). Figs.6 and 7 are oscillograms from which the volt-amper characteristics were derived. A family of volt-ampere characteristics for rectifiers V-15, V-14 and V-13 is shown in Fig.8. There are 8 figures.

S/0001/64/000/013/K001/K002

AUTHOR: Kamenskaya, Ya. A., Shvarts, G. L., Ivanov, Yu. M

TITLE: Corrosion resistance of titanium alloys

SOURCE: Ref. zh. Khimika, Abs. 13K3 27

CITED SOURCE: Tr. Vses. n.-i. i konstrukt. in-t khim. mashinostr., vy"p. 45, 1963, 43-54

TOPIC TAGS: corrosion resistance titanium alloy hydrochloric acid. formic acid.

Alloy: Copper alloy

ABSTRACT: Alloying Ti with a small quantity (0.1-0.2%) of palladium considerably increases its corrosion stability in HCl (concentrations up to 10%), and in boiling formic and oxalic acids (to 50%). Ti alloys with Ta (20% Ta) as well as with Nb (30% Nb) show satisfactory corrosion resistance to boiling solutions of HCl at low concentrations (to 5%) and to formic acid (to 50%). Alloying Ti with molybdenum (to 0.5%) increases the corrosion resistance in HCl (to 10%) and H_2SO_4 . Alloying Ti with copper (1.5 and 5% Cu) increases its corrosion resistance in organic acids. All the experimental Ti-based alloys studied were unstable in 65-78% H_2SO_4 except for the alloy with 30% Mo, which gave inconsistent results. The alloys of Ti with Pd and Nb gave unsatisfactory results during work in friction pairs in 2% HCl and 65% H_2SO_4 . Authors' summary.

"Using an Antimony Microelectrode for the Potentiometric Chromatography of Gasoline-Alcohol-Water Solutions."

Byull, Pol'sk Akad. Nauk, Otd. 3, Vol 1, No 7, pp 297-303, 1953

The antimony electrode can be successfully used for the potentiometric titration of dilute solutions of low acidity of the following non-electrolytes: methyl, n-propyl, n-butyl, and ethyl alcohols and in a mixture of 48% ethyl alcohol, 50% gasoline, and 2% water. When using this mixture, the jump in potential at the equivalence point is especially great. (RZhKhim, No 20, 1954)

TITLE: Modernizing the ATA-40 Spot Welder (Modernizatsiya tochechnoy svarochnoy mashiny ATA-40)

PERIODICAL: Tekhnol. transp. mashinostroyeniya, 1957, Nr 8, pp 55-56

ABSTRACT: In order to permit welding of a reaper canopy on the series-welding ATA-40 spot welder, the bottom holder of the machine is replaced by a support having a plate fastened to the floor of its base. To the base there is fastened an electrode holder to which a bus is connected. The sheets to be welded are mounted on a block. The design of the modernizing modification of the machine is presented. Machine welding of the canopy is more productive and economical than the manual arc welding operation now in use.

TITLE: Heat Treatment and Properties of Large-Size Parts

PERIODICAL: Sb. statey, Ural'skiy z-d tyazh. mashinostr. im. S. Ordzhonikidze, 1958, Nr 5, pp 73 - 89

ABSTRACT: Information is given on heat treatment conditions of large-size 34KhN2M steel forgings of rotors for 50,000 kw turbo-generators where quench-hardening and tempering was replaced by normalization and tempering. The author analyzes defects of heat treatment and their causes revealed by ultrasonic checking. Prevalent defects are: short intermittent cracks or pores located in the "bright" spots and revealed in macro-etching of the forgings. The "bright" spots represent segregational areas, deformed during forging, enriched with P, S and probably also with C and H. On the basis of experimental investigations and industrial tests the heat treatment technology

PHASE I BOOK DESCRIPTION 507/3450

Termichskaya obrabotka i svoystva kuyemicheskikh priborov (Heat Treatment and Properties of Large Forgings), Moscow, Mashgiz, 1959. 165 p. 4,000 copies printed.

Reviewer: E.M. Sokolov, Candidate of Technical Sciences; Ed.: P.V. Shilyuyev, Candidate of Technical Sciences; Tech. Ed.: M.A. Dugina; Exec. Ed.: G.M. Shilovskiy, Division, Mashgiz; A.V. Kolesina, Engineer.

PURPOSE: This book is intended for technical personnel working in the shops, laboratories, and design offices of plants manufacturing heavy machinery and electrical equipment. It may also be of some interest to research personnel.

CONTENTS: This collection of articles describes methods employed by the USSR (Great Heavy Machinery Plant, Sverdlovsk) for heat-treating large forgings. Research conducted at the plant is also discussed. The articles are given in a convenient form for the quenching and normalizing of heavy forgings. A considerable portion of the book is devoted to the mechanical properties of forgings for heavy machinery and one-piece steam-turbine rotors at various points along the length and neck of these parts. The main defects occurring in forgings of these types are described, their causes are analyzed, and methods of preventing them are suggested. The book contains a study of heavy forgings made of vacuum-treated steel and gives, for comparison, a study of heavy forgings made of ordinary steel. References are given. No specialities are mentioned. References accompany most of the articles.

Calculating the Cooling Rate of Heavy Structural Steel Forgings (P.V. Shilyuyev)

Heat Treatment of Motor Forgings (P.V. Shilyuyev, L.I. Krater, Z.I. Masarova)

TITLE: Heat-insulating shells of inflated pearlite

PERIODICAL: Liteynoye proizvodstvo, no. 1, 1963, 4 - 5

TEXT: Investigations were carried out at the TsZL Dnepropetrovskiy zavod metallurgicheskogo oborudovaniya (Dnepropetrovsk Metallurgical Equipment Plant) to study the possibility of using inflated pearlite for heat-insulating shells instead of the exothermic heating of risers. The pearlite sand used ensured high heat-insulating properties because of its low volumetric weight - 120 - 200 kg/m³ - and low coefficient of heat conduction - 0.04 - 0.05 kcal/m · h. The insulating mixture contained (in volume %): 92% inflated pearlite, 8% refractory clay, 7% water glass of 1.48 - 1.52 density. The mixture had a gas permeability of 200 - 500, a compressive strength of 0.4 - 0.8 kg/cm² at 14 - 19% humidity and a tensile strength of 2 - 6 kg/cm². The physico-mechanical properties of this mixture are given in a table. Good technological properties are obtained only if a first-grade pearlite is used. The test results of producing some 500 tons of castings.

A004/A127

varying in weight from 50 to 3,750 kg showed that, as to efficiency, shells of inflated pearlite are equal to carbon-thermite exothermic mixtures, permitting to cut the weight of risers by a factor of 2 compared to the weight of ordinary risers. In addition to this, the authors enumerate a number of other advantages and present some technological details. They point out that the economic efficiency of using heat-insulating shells amounts to 25% in producing steel castings, 15% in case of bronze castings and 20% in the production of high-strength cast iron (relative to the cost of the liquid metal). There is 1 table. ✓

TITLE: Practical Field Training in Physical Geography

PERIODICAL: Vestnik vysshey shkoly, 1959, Nr 5, pp 78 - 79 (USSR)

ABSTRACT: The basic purpose of practical field training is to assimilate the methods of thoroughly conducted geographical research and to estimate the natural resources and possibilities of their utilization on a specific territory. The natural-geographical and geographical departments of pedagogical institute conduct practical field training in physical geography during the first 4 years. The author describes the task given to students of the 4 years which results in working out a detailed geographic characteristic of the specific territory, drawing up a landscape chart with a detailed explanation.

Practical Field Training in Physical Geography

In 1955, the Ministerstvo prosveshcheniya RSFSR (Ministry of Education RSFSR) approved a program of practical field training in summer for third year students which is carried out by the various pedagogical institutes in a different way for lack of information on the content and methods to be adopted. The Geographical Department of the Moscow City Pedagogical Institute has been convinced by experience that it is best to conduct practical field training on a comparatively small territory. It should, however, visually demonstrate the most important regularities of structure of the geographical surrounding and the intercommunication between the individual elements of nature and economy. The geographical and biologic-geographical stations of vuzes comply with these demands. The author outlines how research could be developed if the stations are well equipped, stating that

TITLE: Study of the Spontaneous Contraction of Polymers With Fully Developed Spatial Structure in the Course of Tearing

PERIODICAL: Doklady Akademii nauk SSSR, 1960, Vol. 133, No. 6, pp. 1364-1367

TEXT: The authors wanted to determine the relaxation properties of samples subject to tearing on the basis of the velocity of their spontaneous contraction. The tearing of non-filled vulcanizates from CKH-18 (SKN-18), CKH-26 (SKN-26), and CKH-40 (SKN-40) rubber with different percentage of nitrile groups, but the same degree of interlacing was studied with a time-lapse camera CKC-1 (SKS-1). Two kinds of samples were used: Samples No. 1 had the dimensions 60×50×1 mm, and had a 1 or 2.5 mm deep groove on the longer side. Samples No. 2 were small stripes (60×10×1 mm). In samples No. 1 the rate of contraction was measured of the rest being torn only at the end of the experiment, whereas in samples No. 2 the entire sample was torn after a certain
